13. ABSTRACT (Maximum 200 words) This site investigation report presents the results of the sampling and analysis conducted at the Coal Storage Area Annex. The data are evaluated through a risk-based screening process to determine the potential risks associated with the study area, which is to be surplused. Based on a carcinogenic risk level of 1E-04, the widespread use of coal at the study area, and the consistently elevated levels of PAHs detected in the soil samples, a removal action was recommended for the Coal Storage Area Annex Study Area.

1.0 Introduction

This section of the Site Investigation Report for the Coal Storage Area Annex Study Area (CSA Annex SI) includes a brief description and history of Fort Sheridan and the Surplus Operable Unit (OU) and a discussion of the objectives, scope, and approach for the CSA Annex study area. This CSA Annex SI addresses only the aforementioned CSA Annex study area.

The Sampling and Analysis Plan for this study area referred to it as the CSA2 Annex study area (QST, 1999). However, it appears this study area is separate from CSA2 and lies in between CSA2 and CSA3. Therefore, this study area is more appropriately referred to in this document as the CSA Annex study area.

1.1 Site History

Fort Sheridan is located approximately 25 miles north of Chicago along the western shore of Lake Michigan. The installation location is shown in Figure 1-1. Fort Sheridan, named for General Phil Sheridan, was established in 1887 in the wake of the Great Chicago fire of 1871 and at the request of Chicago city leaders following labor riots of 1886. The installation is bounded by the towns of Highwood to the west, Highland Park to the south, and Lake Forest to the north. Fort Sheridan covers an area of approximately 712 acres. The land occupied by Fort Sheridan is approximately 50 feet above Lake Michigan. The topography is relatively flat and gently sloping toward Lake Michigan. The lake side of the installation terminates in a bluff or embankment that extends the full length of the boundary and beyond.

The Fort Sheridan area has been developed since the mid-1800s and was the site of heavy industry including logging, a lumber mill, leather tanning, brick making, and iron casting (Melichar, 1995). Land was transferred to the government for a token fee of \$10 by three members of the Commercial Club of Chicago: Adolphus Bartlett, Charles Hutchinson, and John Janes. Three ravines at Fort Sheridan are named for these individuals.

Troops trained at Fort Sheridan served in the Spanish-American War in 1898, the Mexican Intervention in 1913, and World Wars I and II. Fort Sheridan was a training center for anti-aircraft artillery units during World War II. From the 1950s until 1974, Fort Sheridan served as maintenance and supply center to NIKE air-defense missile systems for the Chicago, Gary, Detroit, Minneapolis-St. Paul, and Milwaukee air-defense network. Three NIKE missile silos were installed in the northern part of Fort Sheridan. These silos have been largely stripped of equipment and abandoned.

In 1988, the Commission on Base Realignment and Closure (BRAC) recommended Fort Sheridan, Illinois for closure to the Secretary of Defense. The installation ceased military operations as an Army facility in May 1993. Subsequently, portions of the installation were realigned to the U.S. Navy and U.S. Army Reserve. Approximately 100 acres are now owned by the U.S. Army Reserve and used for equipment storage and disbursement, training, and administrative functions. Approximately 200 acres are now owned by the Navy and are used for family housing, administration, vehicle maintenance, communications and training. Approximately 300 acres have been transferred to private ownership, about 40 acres are awaiting property transfer, and the remainder of the installation (approximately 60 acres) is still under Army jurisdiction and will be transferred to private ownership upon completion of environmental investigation and/or restoration activities.

To support decisions regarding preparation of the property for release, the Department of the Army has implemented environmental studies and will conduct restoration activities (if needed) before property transfer. The Army conducts these activities under the Defense Environmental Restoration Program and the BRAC program.

Fort Sheridan was divided into two principal OUs in 1995 to facilitate the implementation of the remedial investigation/feasibility study (RI/FS) and expedite the reuse of surplus Army property under the BRAC program. The first OU, designated the Surplus OU, consists of the excess installation property planned for disposal and reuse. This area occupies the north end of Fort Sheridan and is primarily composed of the golf course and historic district. The second OU is designated the Department of Defense (DoD) OU since this area has been realigned to the U.S. Navy and U.S. Army Reserves. It includes most of the area to the south of Bartlett Ravine and the Army Reserve area in the northwest corner of Fort Sheridan. The boundaries of the two OUs are indicated in Figure 1-2.

A RI/FS is currently being conducted for the Surplus OU at Fort Sheridan. The Surplus OU consists of property that has been declared excess by the Army and will be or has been transferred to the local communities. The CSA Annex study area is located within the Surplus OU (Figure 1-3). The CSA Annex study area is bounded on the east by the U.S. Navy property line, the west by Thorpe Road, and the south by CSA2 (Figure 1-4). This new study area was created to characterize the area in the vicinity of soil Boring B43SB04 that extends south from the southern edge of the CSA3 removal action to CSA2. The area occupied by the CSA Annex is currently leased to the Cities of Highland Park and Highwood. This area will be transferred to the two cities upon completion of the environmental restoration activities. This property is expected to be assigned to residential use.

1.2 Investigative History

Preliminary assessments of Fort Sheridan, conducted in 1982 and 1989, identified several areas on the installation affected by previous landfilling activities; storage and handling of petroleum, oils, and lubricants (POL), as well as other motor pool wastes; former CSAs; and storage and handling of various chemicals [Gross *et al.*, 1982; Argonne National Laboratory (ANL), 1989]. The nature and duration of these activities at Fort Sheridan justified conducting investigation activities to verify and quantify the nature and extent of associated chemical constituents in the environment, perform human health and environmental risk assessments, and, if necessary, evaluate remedial action alternatives leading to individual study area response actions.

During the Phase II RI investigation, soil Boring B43SB04 was completed and sampled. Soil Boring B43SB04 was initially associated with the Building 43 (B43) study area, even though it is located across former Thorpe Road from B43 (see Figure 1-4). This soil boring was completed to assist in the evaluation of a potential solvent release from B43. However, evaluation of the data obtained from B43SB04 and other soil borings collected in the vicinity of B43 indicated that the release was limited to a small area near the entrance to B43 and that B43SB04 was, in fact, located in an area physically and chemically separate from the B43 study area. Elevated levels of polynuclear aromatic hydrocarbons (PAHs) were detected in the surface sample collected from B43SB04. Therefore, additional soil sampling was conducted on April 21, 1999 to delineate the degree and extent of the PAHs within the CSA Annex study area. During this investigation, seven test pits were excavated and sampled within the CSA2 Annex study area.

1.3 CSA Annex SI Objectives

The objectives of the investigations at the CSA Annex study area were to:

1. Characterize the nature and extent of mission-related constituents in the CSA Annex soils;
2. Identify and characterize potential risks posed to human and environmental receptors by means of a conservative risk-based screening process; and
3. Determine, on the basis of the risk-based screening process, whether further evaluation or action is necessary to protect human health and the environment.

2.0 Study Area Investigations and Results

The investigation activities presented in this CSA Annex SI were conducted in consultation with representatives from the U.S. Environmental Protection Agency (USEPA) and Illinois EPA (IEPA). These two agency representatives, together with the Fort Sheridan BRAC Environmental Coordinator (BEC), comprise the BRAC Cleanup Team (BCT).

2.1 Test Pit Excavation and Sampling

Seven test pits were excavated in the CSA Annex study area on April 21, 1999 with a backhoe. The location, length, and orientation of the test pits are shown in Figure 1-4. The test pits were excavated in accordance with the protocols and procedures in Section 4.4.1 of the Overall Quality Assurance Project Plan (OQAPP) (ESE, 1995) and the Health and Safety Plan (HASP). Test pits were excavated to a depth of 3 feet below ground surface (ft-bgs) unless a coal layer was encountered. In those instances where a coal layer was encountered, the test pit was excavated to at least 1 foot below the coal layer or 3 ft-bgs, whichever was deeper. Completed test pits were backfilled and packed.

Five samples were collected from each test pit: one scrape sample from each of the four sidewalls and one grab sample from the floor of the test pit. The sidewall sample scrapes typically started below a surface layer of gravel and extended to the bottom of the excavation. The first step in collecting the scrape samples was to clean off the sample scrape area with a stainless-steel spoon to remove material that had been smeared against the sidewall by the backhoe during the excavation. Each sidewall sample was collected by scraping off sidewall material with a spoon into a stainless-steel bowl. The material was then mixed in the bowl before placement in the glass sample jars. Floor samples were collected from the top 6 inches of material in the center of the test pit floor using a sample spoon. The collected material was placed into a stainless-steel bowl and mixed. The mixture was then placed in the sample jar.

Sample spoons and bowls were decontaminated by washing in a deionized water (DI)/Liquinox™ solution followed by a DI water rinse after each use. The backhoe bucket and arm were steam-cleaned over the test pit just excavated, thus collecting the wash water in the test pit. After collection and packaging, the samples were shipped on ice via Federal Express Overnight to the Quanterra Environmental Services Laboratory in St. Louis, Missouri. The samples were analyzed for PAHs by USEPA Method 8310.

Previous investigations conducted at the CSA2 and CSA3 study areas have determined that concentrations of inorganic constituents at these study areas are at background concentrations and the

PAHs are the only constituents of concern at these study areas (QST, 1997a and 1997b). Therefore, it is reasonable to assume that, given mission-related activities conducted at the CSA Annex study area were the same as those conducted at CSA2 and CSA3, inorganic constituents would be at background concentrations at the CSA Annex study area. Therefore, samples were only analyzed for PAHs.

2.2 Field Observations

The nature of the geology encountered in each test pit was recorded in the field logbook by the geologist at the time of excavation. Test pit logs are presented in Appendix A. Field observations are summarized in the following paragraphs.

Test Pits AXTP1A, AXTP1B, and AXTP1C

Test pits AXTP1A, AXTP1B, and AXTP1C encountered concrete slabs at approximately 0.5- to 1-foot below existing grade. These concrete slabs may be contiguous with the concrete observed in test pit AXTP05, discussed below (see Figure 1-4). A brick-lined manhole was encountered on the northern edge of AXTP1C. The fill over the concrete slabs at test pit AXTP1A consisted of a mixture of soil, gravel, and coal fill. The fill over the concrete at test pit AXTP1C consisted predominantly of coal fill.

Test pit AXTP1B was completed adjacent to B43SB04 (see Figure 1-4). This test pit was approximately 14 feet long and a maximum of 6 feet deep (see Appendix A). The western wall of test pit AXTP1B consisted of approximately 8 inches of gravel, followed by about 1.25 feet of coal/cinder fill, which was underlain by 4.33 feet of brown native clay (till). The eastern wall had a different composition consisting of approximately 8 inches of gravel, underlain by approximately 3.5 feet of coal/cinder fill mixed with clay fill, which in turn was underlain by 2 feet of native clay. The northern wall of the test pit consisted of approximately 3.5 feet of gravel/rock fill underlain by native clay. The southern wall consisted of approximately 10 inches of gravel underlain by 2.3 feet of clay/gravel fill, followed by native soil. The scrape started below the surface gravel (8 to 10 inches) and extended to the bottom of the excavation. The sample scrape on the northern wall started at 3.5 feet below grade.

Test pit AXTP2 was located north of B43SB04 and encountered clean backfill that was placed after the CSA3 removal action effort. This effort is discussed in detail in the Draft Non-Time Critical Removal Action Completion Report, Buildings 42, 43, 77, and Coal Storage Area 3 (IT, 1999). A test pit log was not generated for this test pit.

Test pit AXTP3 was completed east of B43SB04 and was approximately 9 feet long and 3 feet deep. The lithology encountered was similar for each of the test pit walls. A surface layer of approximately 8 to 12 inches of gravel/clay fill was underlain by 6 inches of coal/cinder fill. This in turn was

underlain by approximately 2 to 2.5 feet of native clay. The south lithology was slightly different with approximately 10 inches of clay fill (little or no gravel), which was underlain by approximately 1 foot of coal fill before encountering native clay.

Test pit AXTP4 was completed southeast of B43SB04 and was approximately 13 feet long and 4 feet deep. Similar lithology was encountered at each of the test pit walls. The lithology consisted of approximately 8 to 10 inches of gray-brown clay soil followed by approximately 1.5 feet of coal/cinder fill, which, in turn, was followed by native clay. Only 1 inch of clay soil was present at the top of the west wall.

Test pit AXTP05 encountered a concrete slab at approximately 8 to 10 inches below grade. As stated above, the concrete encountered in test pit AXTP05 may be contiguous with the concrete observed in test pits AXTP01A and AXTP01C. The lithology in test pit AXTP05 was logged in samples collected from two walls to determine the nature of the fill over the concrete. Due to the excavation procedure and fill encountered, only the north and east walls allowed logging and sampling. The north wall contained approximately 3 inches of surface gravel, followed by 3 inches of coal fill and then approximately 10 inches of clay/rock fill. The east wall consisted of approximately 3 inches of gravel fill, followed by 2 inches of coal fill, then 3 inches of clay/rock fill.

2.3 Laboratory Analytical Results

A summary of the analytical results for the Phase II RI soil boring B43SB04 as well as results from the test pit sampling are presented in this section. The analytical data sheets are presented in Appendix B.

2.3.1 Data Validation

Analytical data were validated in accordance with the National Functional Guidelines (USEPA, 1994). The results of the data validation are contained in Appendix C. As a result of the validation, the concentrations reported for Samples AXTP1BS and AXTP3E are qualified J (i.e., estimated).

2.3.2 Analytical Results

Organic constituents detected above method detection limits in CSA2 Annex soil samples are presented in Table 2-1. Only samples from Boring B43SB04 were analyzed for inorganic constituents. These results were previously reported in the Final Sampling Results and Data Evaluation Report for Miscellaneous Surplus OU Study Areas (Miscellaneous Study Areas DER) (QST, 1997a). The inorganic constituent concentrations detected are similar to site-specific background values.

Except for Sample AXTP3F, each sample contained detectable levels of at least one PAH constituent. Benzo(a)pyrene concentrations ranged from 0.003 milligrams per kilogram (mg/kg) to 9.3 mg/kg. The highest concentration was detected in Sample AXTP5E, the scrape from the east wall of Test Pit AXTP05. Twelve of the 18 detections of benzo(a)pyrene were at or above 1 mg/kg. The PAH constituent with the highest reported concentration is anthracene with 32 mg/kg, followed by acenaphthene at 25 mg/kg, phenanthrene at 16 mg/kg, pyrene and fluoranthene at 14 mg/kg, and naphthalene at 12 mg/kg. Each of these detections were reported for Sample B43SB04(0'). The detection of elevated levels of PAHs is not unexpected given the presence of coal in sidewalls of the test pits.

n\data\proj\4902087\sp\CS424\annexPAH_HitsOnly.xls

N/A = Not applicable

mg/kg = milligrams per kilogram

J = Value is estimated (NFG Qualifier)

UJ = The analyte/compound is not detected above the reported sample quantitation limit. The reported quantitation limit is approximated and may not represent the actual limit necessary to accurately measure the compound in the sample (NFG Qualifier).

3.0 Risk-Based Screening Evaluation

The data obtained from soil Boring B43SB04 and the excavated test pits are used in this report to determine the potential risk associated with this study area, which is to be surplused. To achieve this determination, each datum was evaluated using the risk-based screening process outlined in the Final Revised Final Technical Evaluation Plan (TEP) (ESE, 1996). This section presents the results of this process.

3.1 Data Evaluation Baseline

Prior to actually performing the screening, the issue of duplicate samples was addressed. Duplicate samples were collected for quality control (QC) purposes. In those instances where a constituent was detected in both the primary and the duplicate samples, the concentrations were averaged. The average concentration was then carried through the risk-based screening. In those instances where a constituent was detected in one sample but not the other, the value represented by the detected concentration was used. This concentration was then carried through the risk-based screening. Samples that exceeded the risk-based screening values were incorporated into a relative-risk analysis identical to that used in the Miscellaneous Study Areas DER and Technical Memorandum (QST, 1997a and 1997b).

3.2 CSA Annex Study Area Risk-Based Screening

A total of 19 soil samples were utilized in the risk-based screening process. Duplicate samples were collected from two of the 19 samples. Each of the 19 samples were analyzed for PAHs and three of the 19 samples were analyzed for inorganic constituents. The results of the risk-based screening for the CSA Annex are presented in Table 3-1. Inorganic constituents were not evaluated in the risk-based screening as they have previously been determined to be at background levels (QST, 1997a and 1997b). In Table 3-1, the terms "fail" and "pass" are used to describe the results of the screening. The term "fail" indicates that the constituent concentration is above or exceeds the risk-based screening value. The term "pass" indicates that the constituent concentration is lower than or falls below the risk-based screening value.

PAH constituents exceed the risk-based screening values in 15 of the 19 samples collected. Benzo(a)pyrene is the most common PAH exceeding the risk-based screening value with 15 exceedences. Dibenz(a,h)anthracene is the second most common PAH exceeding the risk-based screening value with 12 exceedences followed by 11 benzo(a)anthracene and benzo(b)fluoranthene exceedences.

Indeno(1,2,3-cd)pyrene exceeded the risk-based screening value with six exceedences. The screening criteria used are USEPA Region IX Preliminary Remediation Goals (PRGs).

3.3 Risk Evaluation

Results of the CSA Annex risk calculations are presented in Table 3-2. These results indicate that the RS_{ct} associated with the CSA Annex study area samples is 1E-04. The principle components of the RS_{ct} are benzo(a)pyrene with an RS_c of 6E-05 (60 percent of the RS_{ct}), benzo(a)anthracene with an RS_c of 2E-05 (20 percent of the RS_{ct}), and dibenzo(a)anthracene with an RS_c of 2E-05 (20 percent of the RS_{ct}). The RS_{ct} of 1E-04 for the CSA Annex is based on residential risk-based screening values, which, in accordance with the approved Fort Sheridan Concept Plan [Johnson, Johnson and Roy, Inc. (JJR), 1994], are appropriate for the future use of this study area.

UCL = 95 percent Upper Confidence Limit of the mean concentration

mg/kg = Milligrams per kilogram

* = The lower of the UCL or maximum concentration is used.

** = Value listed is the UCL for the constituent

4.0 Conclusions and Recommendations

The RS_{ct} of 1E-04 for the CSA Annex study area is at the upper end of USEPA's target risk range. Although the use of generic, conservative risk-based screening values to calculate the risk likely results in an overestimation of the potential risks, the widespread presence of coal at the study area (about 4 feet thick in one test pit) and the consistently elevated levels of PAHs detected in the samples, indicates a strong potential for unacceptable risks to future residents. Coal was open-air stockpiled in the general area and was used to supply fuel for industrial heating purposes at Fort Sheridan. Therefore, a removal action is recommended for the CSA Annex study area.

INTRODUCTION

Twenty-two (22) soil samples from QST were received at Quanterra Environmental Services, Earth City, MO for PAH analysis. The list of analytical tests performed, as well as date of receipt and analysis, can be found in the attached report.

ANALYTICAL RESULTS/METHODOLOGY

The analytical results are presented by analytical test in the attached packages and summary reports. This report includes information on client identification numbers, lab identification numbers, preparation date, analysis date, results, units, and results for quality control samples.

The following table is a list of the analyses requested, and the methods used for the above samples:

<u>Analysis</u>	<u>Method</u>
PAH	EPA 8310
Percent Moisture	ITAS/SOP

PAGE 3 of 4

April 30, 1999

Quanterra Project Number : 833.02

QUALITY CONTROL

Method blanks, laboratory control samples, matrix spike, and matrix spike duplicate were analyzed for each parameter listed above.

NONCONFORMANCES

PAH

Batch QC (MS/MSD) was extracted on one set of samples and was not performed on QST's 2nd batch of samples. A LCS and blank was associated with both batches. Quanterra is providing QC (MS/MSD) data on an additional batch extracted on the same day and analyzed under the same calibration per the clients request. A PAH addendum data package was provided.

COMMENTS

PAH

The MS/MSD was out of control limits due to a dilution being made because of hits in the sample.

Receipt

The samples were received at 5°C. Sample CSA3SDW3 on chain of custody read as CSA3W3 on the sample lid and was logged in as such.

QUALIFIERS

- * = Values reported outside the QC limits.
- B = Value greater than IDL but less than CRDL (Metals only)
- B = Analyte found in the blank,(Organics only)
- CRDL = Customer Required Detection Limit
- DL = PQL
- D = Diluted
- E = Exceeds calibration
- IDL = Instrument detection limit
- J = Estimated Value (Organics only)
- MDA = Minimal detectable activity
- MG/L = Milligrams per liter
- MG/KG = Milligrams per kilogram
- NA = Not applicable
- NC = No criteria at this time

PAGE 4 of 4

Quanterra Project Number : 833.02

QUALIFIERS-continued

ND	= Non - detect
PCI/L	= Picocuries per liter
PCI/G	= Picocuries per gram
U	= Non - Detect
UG/L	= Micrograms per liter
UG/G	= Micrograms per gram
UG/KG	= Micrograms per kilogram
RPD	= Relative Percent Difference
%REC	= Percent Recovery
QCBLK	= Method Blank
QCLCS	= Laboratory Control Sample

1.0 Introduction

Twenty-two soil samples from the Coal Storage Area (CSA) Annex and the CSA3 sand sampling were prepared and analyzed by Quanterra Inc. (Quanterra) of Earth City, Missouri. The samples were collected on April 21, 1999. The samples were analyzed for polynuclear aromatic hydrocarbons (PAHs) by U.S. Environmental Protection Agency (USEPA) SW-846 Method 8310. The data package received from Quanterra for the soil samples contained a Quality Control Report, but additional quality assurance/quality control information necessary to complete the data review was requested and received from Quanterra under separate cover.

This report presents the results of the analytical level III and level IV data review performed on the 22 soil samples in accordance with the National Functional Guidelines (NFG) for Organic and Inorganic Data Review (USEPA, 1994). The analytical level IV data review was conducted by randomly selecting five samples (or 23 percent) from the 22 samples. The five selected samples were:

<u>Client ID</u>	<u>Lab ID</u>
AXTP1BS	21165-002
AXTP3E	21165-009
AXTP3S	21165-011
AXTP4F	21165-016
CSA3SDW1	21165-019

The analytical sample data were evaluated using the information obtained regarding the following parameters: chain of custody, sample condition receipt report, extraction holding times, analysis holding times, instrument performance check, initial calibration, continuing calibration, blanks, system monitoring compounds (surrogates), matrix spikes/matrix spike duplicates, laboratory control samples, and internal standards (see attached Data Review Checklist). This data validation report discusses areas of concern and any overall issues that affect data quality. Data sample results affected are qualified as necessary in accordance with the NFG.

2.0 Data Validation and Results

Sample chain of custodies were completed and signed by appropriate parties. Sample arrival at laboratory noted no exceptions in sample arrival conditions. All samples were extracted and analyzed within method holding times. The set of 22 samples was analyzed in two batches (198052 and 198053). The batches contained the samples as listed below.

Batch 198052				Batch 198053	
Sample ID	Laboratory ID	Sample ID	Laboratory ID	Sample ID	Laboratory ID
AXTP1BW	21165-001	AXTP3E	21165-009	CSA3SDW1	21165-019
AXTP1BW MS	21165-MS	AXTP3F	21165-010	CSA3W3	21165-020
AXTP1BW MSD	21165-MSD	AXTP3S	21165-011	AXTP5N	21165-021

AXTP3W	21165-008	AXTP5N	21165-018		

2.1 Validation of Batch 198052

The method blank was non-detect for all analytes. The laboratory control sample for this batch had all analytes within the QC recovery acceptance limits for the method. Both method blank and laboratory control samples had system monitoring compounds (surrogates) that were within the method QC recovery acceptance criterion (26-106%).

A minor issue on the review of the sample batch was the associated matrix spike (MS) and matrix spike duplicate (MSD) results. The 16 MS sample analytes were not within the QC percent recovery limits as set by the method. The MSD sample was not within the QC recovery limits for 13 of the 16 analytes. The MS/MSD had 2 analytes (chrysene and acenaphthene) that were not within the relative percent differences (RPD) criterion of 25%. No data qualification was made based on the MS/MSD data alone.

The two continuing calibrations for this batch had percent differences that were greater than 15% between the initial and continuing calibration responses for acenaphthene (29.5%, 28.1%) and anthracene (18.8%, 16.8%). Thus, all associated positive detects for acenaphthene and anthracene have been qualified as estimated "J" for the associated samples. The associated samples are 21165-001, 21165-

001MS, 21165-001MSD, 21165-002, 21165-005, 21165-006, 21165-007, 21165-009, 21165-013, 21165-014, 31165-015, 21165-021, and 21165-022.

In addition, samples 21165-001, 21165-001MS, 21165-001MSD, 21165-002, 21165-005, 21165-006, 21165-007, 21165-009, 21165-013, 21165-014, 31165-015, 21165-021, and 21165-022 were found to have system monitoring compounds (surrogates) that were not within the QC acceptance criterion of 26-106%. There were little or no recoveries for these samples because the recoveries were diluted out. In this case, the associated positive sample results and detection limits/non-detects have been qualified as estimated, "J" or "UJ", respectively.

2.2 Validation of Batch 198053

The method blank was non-detects for all analytes. The laboratory control sample for this batch had all analytes within the QC recovery acceptance limits for the method. Both method blank and laboratory control samples had system monitoring compounds (surrogates) that were within the method QC recovery acceptance criterion (26-106%).

The matrix spike (MS) and matrix spike duplicate (MSD) results for this batch were within the QC percent recovery limits as set by the method. The MSD sample was also within the QC recovery limits for the 16 analytes. The MS/MSD had relative percent differences (RPD) that were within the QC acceptance criterion of 25%.

The continuing calibrations for this batch had percent differences that were within 15% between the initial and continuing calibration responses.

The system monitoring compounds (surrogates) for the samples in this batch were within the QC acceptance criterion of 26-106%.

QC in this batch met the required specifications so no action was taken and no samples associated with this batch were qualified.

3.0 Summary and Conclusions

The result of the validation of the 22 soil samples resulted in several of the samples being qualified (see attached data sheets). The qualifiers that were placed on the data were "J" and "UJ". Qualifier "J" means that the associated numerical value is the approximate concentration of the analyte in the sample. Qualifier "UJ" means that the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.

Data Review Checklist

The data requirements to be checked are listed below:

- Holding Times
- Initial Calibration
- Continuing Calibration
- Blanks
- System Monitoring Compounds
- Matrix Spikes/Matrix Spike Duplicates
- Laboratory Control Samples
- Internal Standards

The specific Criteria, Evaluation, and Action for each requirement listed is per the National Functional Guidelines.

QST
11655 Lilburne Prk Road
St. Louis, MO 63146

Project: 833.02

Category: PAH
Method: EPA 8310
Matrix: Soil

Sample Date : 04/21/99
Receipt Date : 04/22/99
Report Date : 04/30/99
Quanterra ID : 21165-022

Client ID: AXTPSE

Analyte	CAS Number	Blank Sample Name	Prep. Date	Analyses Date	Result	Unit	Qual.	Detection Limit	Dilution
